Overview of cortical blindness

Cerebral visual impairment (CVI) is defined as vision loss resulting from damage to the retrogeniculate pathway, in the absence of damage to the anterior afferent visual pathways or ocular structures, or vision loss that is greater than expected for the degree of ocular pathology. CVI has become the leading cause of visual impairment in children in developed countries. Approximately 30-40% of children with visual impairments have CVI. The National Institutes of Health website cites CVI prevalence of 10.5% of all children with developmental disabilities.
